Course logistics

- ➤ You have less than *one week* for your first homework
- Submit your implementation, even if you completed it *partially*

Understanding Full Virtualization, Paravirtualization, and Hardware Assist

- > You should read VMWare white paper
 - ➤ There will be exam questions from the paper (up to page 10)

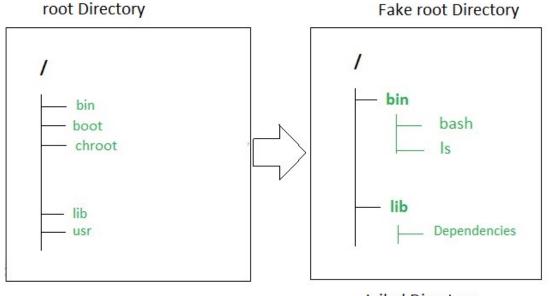

- Creating different and separated execution environments for applications that are managed concurrently.
- ➤ OS kernel allows for multiple isolated user space instances.

	Is there hypervisor?	How many OSs are involved?
Hardware-level	YES	Multiple OSs
OS-level	NO	Single OS

- The kernel is also responsible *for*
 - Sharing the system resources among instances
 - Limiting the impact of instances on each other.
- >A user space instance contains a proper view of
 - the file system, which is completely isolated
 - separate IP addresses
 - software configurations
 - access to devices.

- ► An evolution of the **chroot mechanism** in **Unix systems**.
 - Changes the file system root directory for a process and its children.
 - The process and its children cannot have access to other portions of the file system than those accessible under the new root directory.

- Unix systems expose devices as parts of the file system
 - Using *chroot* it is possible to completely *isolate a set of processes*
- > Following the same principle, operating system-level virtualization aims to provide separated and multiple execution containers for

running applications.

multiple application servers share the same technology:

- When different application servers *are aggregated* into *one*physical server, each server is run in a different user space,
 completely isolated from the others.

A container is an isolated virtual env. which can run an application.

کے قبتی مک عکس رو المام مکنم و روی میک antainer اوبات کنم همی برنامه های مانوش های منافش های منافش های منافش های منافق منافق

Several containers can be created on each operating system, to each of which a *subset of the computer's resources* is allocated.

➤ Programs running inside a container can only see the container's contents and devices assigned to the container.

Docker

- Docker is the company driving the container movement.
- ➤ A container image is

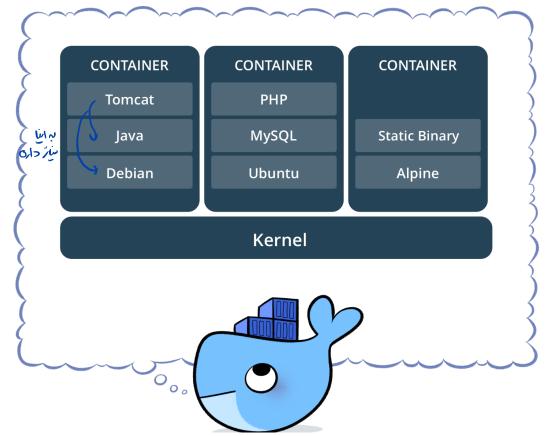

- It includes everything needed to run it: code, runtime, system tools, system libraries, settings.

Available for both Linux and Windows based apps, containerized software will always run the same, regardless of the environment.

Containers vs. Virtual Machines

➤ Virtual machines (VMs) are an abstraction of physical hardware turning one server into many servers.

A VM includes a full copy of an operating system, one or more apps, necessary binaries & libraries-taking up tens of GBs.

►VMs can also be *slow to boot*.

Containers vs. Virtual Machines (Cont.)

- Containers are an abstraction at the app layer that packages code and dependencies together.
- ➤ Multiple containers can run on the same machine and share the OS kernel with other containers.
 - each running as isolated processes in user space.
- Containers take up less space than VMs
 - Container images are typically tens of MBs in size
 - Start almost instantly.

Docker Technology

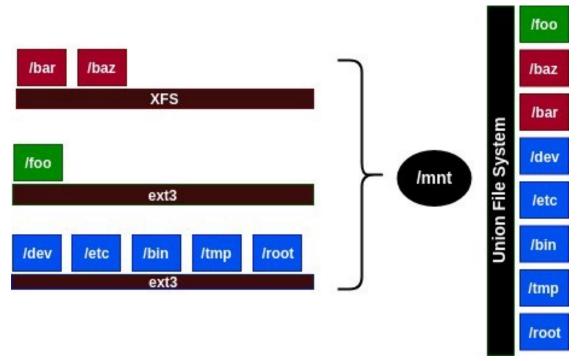

Virtualization

17

Docker Technology

- ➤ Docker is developed **primarily for Linux**, where it uses the resource isolation features of the Linux kernel such as:
 - cgroups and kernel namespaces,
 - and a <u>union-capable file system</u> such as OverlayFS and others.

Docker Technology- cgroups

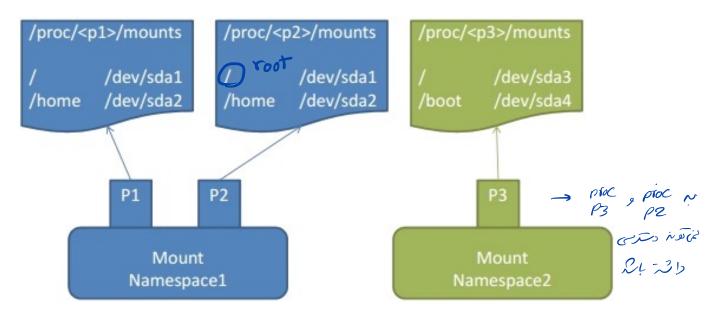

➤ cgroups (abbreviated from control groups) is a Linux kernel feature that limits, accounts for, and isolates the resource usage (CPU, memory, disk I/O, network, etc.) of a collection of processes.

Docker Technology- Namespaces - ProcED Mount

Feature of the Linux kernel that partitions kernel resources such that one set of processes sees one set of resources while another set of processes sees a different set of resources.
